CLAIMS

What is claimed is:

5

10

1. A system for adjusting the position of a head relative to a track on a rotatable storage medium, comprising:

a rotatable medium including at least one surface having a servo pattern contained thereon, the servo pattern containing a plurality of concentric quadrants and a plurality of servo wedges;

a positioning mechanism adapted to determine any misplacement of a portion of the servo pattern in one of the servo wedges, and the quadrant containing that portion; and

a write mechanism adapted to write information regarding the misplacement and quadrant to the servo wedge containing that portion.

15 2. A system according to claim 1, wherein:

the rotatable medium includes a servo pattern containing a plurality of servo bursts, and the portion of the servo pattern includes at least one burst.

20 3. A system according to claim 2, wherein:

the rotatable medium includes a servo pattern containing a plurality of servo bursts, and the portion of the servo pattern includes a burst boundary.

4. A system according to claim 2, wherein:

the rotatable medium includes a servo pattern containing a plurality of servo bursts, and the portion of the servo pattern includes a pair of servo bursts.

30 5. A system according to claim 1, further comprising:

a head containing the write element.

6.	A system according to claim 5, wherein:
	the head further contains a read element.

7. A system according to claim 5, wherein:

the rotatable medium includes a servo pattern containing a plurality of servo boundaries, and each boundary is adapted to be used for positioning the head relative to the rotatable medium.

8. A system for determining servo pattern misplacements, comprising:

a rotatable medium capable of storing information written to the rotatable medium;

a read element capable of reading information from the rotatable medium:

a write element capable of writing information to the rotatable medium; and

a control mechanism in communication with the read element and write element, the control mechanism adapted to:

determine any misplacement of a portion of a servo pattern on a rotating medium;

identify a quadrant on the rotating medium containing the portion; and

store information about the misplacement and the quadrant to be used in any of a read operation and write operation that determines position using that portion of the positioning pattern, such that the misplacement information is only used for that quadrant.

9. A system according to claim 8, further comprising:

a servo controller adapted to determine the misplacement.

10. A system according to claim 8, wherein:

the write element is further adapted to write information about the misplacement and quadrant to the quadrant on the rotating medium containing the positioning pattern.

5 11. A system for reducing written-in runout in a servo pattern on a magnetic hard disk, comprising:

means for determining the misplacement of a servo burst pair on a rotating hard disk;

means for identifying the quadrant containing the servo burst pair, the rotating hard disk having a plurality of quadrants extending radially across a surface of the disk; and

means for storing information about the misplacement of the burst pair and the quadrant to be used in any of a read operation and write operation that determines position using that burst pair, such that the misplacement is only used for that quadrant.

12. A system for removing servo burst misplacement, comprising:

a rotatable medium including at least one surface having a servo pattern contained thereon, the servo pattern containing a plurality of concentric quadrants and a plurality of tracks;

a positioning mechanism adapted to determine any misplacement of a portion of the servo pattern relative to one of the tracks, and the quadrant containing that portion; and

a write mechanism adapted to write information regarding the misplacement and quadrant to the track containing that portion.
